CSC 212: Data Structures and Abstractions 09: Priority Queues

Prof. Marco Alvarez

Department of Computer Science and Statistics University of Rhode Island

Spring 2025

Priority queues

Announcements

• Assignment 2

- purpose of the assignment is to learn how to solve problems with stacks, queues, and deques
- at least one of those data structures should be used on each of the problems
- ✓ designing a good algorithm is more important than coding
- try designing your own solution first, test it on paper

• Spring break plans?

- ✓ ideas for further developing your C++ skills
- **OOP, templates, pointers:** implement your own templated versions of stack, queue, deque, and priority queues (use rigorous testing)
- **problem solving:** solve as many Kattis/LeetCode problems as possible

Priority queues

Definition

- a <u>priority queue</u> is a linear data structure that functions like a queue but with priorities assigned to elements
- elements with **higher priority** are dequeued before elements with lower priority

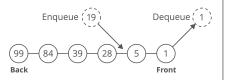

Main Operations

- enqueue: add an element with an associated priority
- dequeue: remove and return the highest priority element

Applications

- ✓ algorithms for graphs
- ✓ event-driven simulation
- search methods in artificial intelligence
- ✓ job scheduling in operating systems, etc.

2

4

Implementation

- Key-value pairs
 - elements in a priority queue can be implemented as a collection of <key,value> pairs
 - key: determines priority, value: associated data

| Operations (min-pq) | Return value |
|---------------------|--------------|
| enqueue(5, A) | |
| enqueue(10, D) | |
| enqueue(3, B) | |
| dequeue() | (3, B) |
| enqueue(7, C) | |
| dequeue() | (5, A) |
| dequeue() | (7, C) |
| size() | 1 |
| isEmpty() | FALSE |

Implementation

- Array-based (unsorted array)
 - \checkmark enqueue at the end O(1) cost (amortized cost if using a dynamic array)
 - \checkmark dequeue (extract max/min) O(n) cost
 - requires searching the entire array
- Array-based (sorted array)
 - \checkmark enqueue at position O(n) cost
 - requires finding position for insertion and shifting elements
 - \checkmark dequeue (extract max/min) O(1) cost
- Binary heap (array)
 - √ most common and efficient
 - \checkmark enqueue $O(\log n)$ cost
 - \checkmark dequeue (extract max/min) $O(\log n)$ cost
 - \checkmark can also build a binary heap from an array in O(n) cost

Implementation

- Using arrays
 - ✓ ensure enqueue and dequeue work efficiently
 - ✓ array can be fixed-length or a dynamic array (additional cost)
- Considerations
 - ✓ highest priority can be defined in different ways
 - in a max-priority queue, the highest priority is the largest priority
 - in a min-priority queue, the highest priority is the smallest priority
 - for equal priorities, the <u>order of elements</u> is determined by the underlying implementation
 - in some implementations, equal priority elements are served following FIFO order
 - in other implementations, the order of elements with the same priority is undefined
 - ✓ underflow: throw an error when calling dequeue on an empty queue
 - overflow: throw an error when calling enqueue on a full queue

```
std::priority queue
           Defined in header <queue>
          template<
               class T.
               class Container = std::vector<T>,
class Compare = std::less<typename Container::value_type>
         > class priority_queue;
       The priority queue of is a container adaptor that provides constant time lookup of the largest (by default) element, at the
       expense of logarithmic insertion and extraction.
       A user-provided Compare can be supplied to change the ordering, e.g. using std::greater<T> would cause the
       smallest element to appear as the top().
       Working with a priority queue is similar to managing a heap in some random access container, with the benefit of not
       being able to accidentally invalidate the heap.
  Member functions
                   constructs the priority_queue
 (constructor)
                                                                                 #include <iostream>
                    destructs the priority queue
                                                                                 #include <queue>
                     assigns values to the container adaptor
Element access
                                                                                       std::priority_queue<int> pq1;
                    accesses the top element
                                                                                      pq1.push(5);
std::cout << "pq1.size() = " << pq1.size() << '\n';</pre>
Capacity
                                                                                      std::priority_queue<int> pq2 {pq1};
std::cout << "pq2.size() = " << pq2.size() << '\n';</pre>
                    checks whether the container adaptor is empty
                    returns the number of elements
 size
                                                                                      std::vector<int> vec {3, 1, 4, 1, 5};
std::priority_queue<int> pq3 {std::less<int>(), vec};
std::cout << "pq3.size() = " << pq3.size() << '\n';</pre>
Modifiers
                    inserts element and sorts the underlying container
                    inserts a range of elements and sorts the underlying contained
                                                                                      for (std::cout << "pq3 : "; !pq3.empty(); pq3.pop())
   std::cout << pq3.top() << ' ';
std::cout << '\n';</pre>
                    constructs element in-place and sorts the underlying containe
 emplace (C++11)
                     removes the top element
 swap (C++11)
                                   https://en.cppreference.com/w/cpp/container/priority_queue/priority_queue/
```

Practice

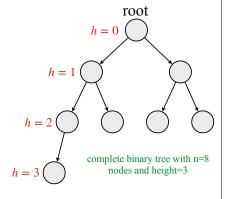

• What is the output of this code?

```
#include <iostream>
#include <queue>
#include <utility> // for std::pair
int main() {
    // default priority_queue - max-heap behavior
    std::priority_queue<std::pair<int, std::string>> pq;
    pq.push(std::make_pair(3, "Job 1"));
    pq.push(std::make_pair(1, "Job 2"));
pq.push(std::make_pair(5, "Job 3"));
    pq.push(std::make_pair(2, "Job 4"));
    pq.push(std::make_pair(7, "Job 5"));
    pq.pop();
    pq.pop();
    pq.push(std::make_pair(7, "Job 6"));
pq.push(std::make_pair(7, "Job 7"));
    while (! pq.empty()) {
         std::pair<int, std::string> top = pq.top();
         std::cout << top.second << std::endl;</pre>
         pq.pop();
    return 0;
```

Binary heaps

Complete binary tree

- Binary tree
 - tree data structure in which each <u>node</u> has at most two children, referred to as the <u>left child</u> and the <u>right</u> child
- · Complete binary tree
 - binary tree in which every level, except possibly the last, is completely filled
 - all nodes in the last level are as far left as possible

The height of a complete binary tree with n nodes is $\lfloor \log_2 n \rfloor$

Practice

- Consider a complete binary tree of height h
 - what is n_{max} , the max number of nodes in the tree as a function of h?
 - hint: use a summation formula
 - what is n_{min} , the min number of nodes in the tree as a function of h?
- For a complete binary tree the following inequality holds: $n_{min} \le n < n_{max} + 1$
 - \checkmark take the logarithm (base 2) of this inequality and express h in terms of n

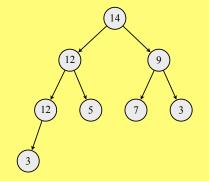

12

Binary heap

- Definition
 - ✓ **structure property**: a binary heap is a **complete binary tree**
 - <u>heap property</u>: each node's value is greater/smaller than or equal to its children's
 - a binary heap can be a **max-heap** (greater or equal) or a **min-heap** (smaller or equal)
- Considerations
 - \checkmark the height of a binary heap is $\lfloor \log_2 n \rfloor$
 - \checkmark the number of nodes at each level h is at most 2^h
 - the number of nodes in a heap is at most: $\sum_{i=0}^{h} 2^{i} = 2^{h+1} 1$

Max-heap example

- · Check:
 - √ structure property
 - √ heap-order property
- · Add 3 elements
- ✓ without violating properties

- · Change 2 values
 - ✓ that violate the heap property

Array representation

- A binary heap can be represented as an array
 - root is at index 0
 - ✓ **last element** is at index n-1
- For any node at index i:
 - \checkmark **left child** is at index 2i + 1
 - \checkmark right child is at index 2i + 2
 - \checkmark parent is at index (i-1)//2

Enqueue (max-heap)

• Algorithm (min-heap is analogous)

2. for each node from parent(n-1) to 1

steps 2-3-4 can be implemented as a function called

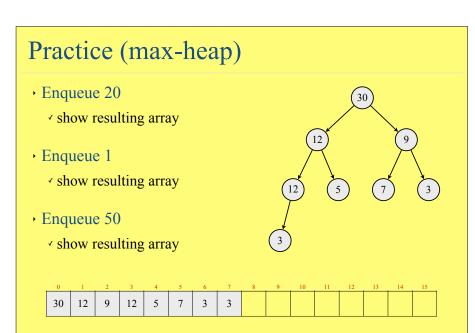

1. append the element to the end of the array

upHeap

- 3. if the element is greater than its parent, swap them
- 4. repeat 2-3 until the element is in the correct position (heap-order restored)
- Time complexity
 - \checkmark how many swaps are necessary? $O(\log n)$

https://visualgo.net/en/heap

1.6

Dequeue (max-heap)

- Algorithm (min-heap is analogous)
 - 1. replace the root with the last element

steps 3-4-5 can be implemented as a function called downHeap

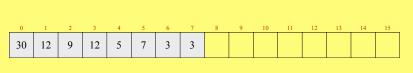

- 2. remove the last element from the array
- 3. compare the root with its children
- 4. if the root is less than either child, swap it with the larger child
- 5. repeat 3-4 until the root is in the correct position (heap-order restored)
- Time complexity
 - \checkmark how many swaps are necessary? $O(\log n)$

https://visualgo.net/en/heap

18

Practice

- Dequeue
 - √ show resulting array
- Dequeue
 - ✓ show resulting array
- Dequeue
 - ✓ show resulting array

Performance

| Method | Unsorted Array | Sorted Array | Binary Heap |
|---------|----------------|--------------|-------------|
| Enqueue | 0(1) | 0(n) | O(log n) |
| Dequeue | 0(n) | 0(1) | O(log n) |
| Max | 0(n) | 0(1) | 0(1) |
| Size | 0(1) | 0(1) | 0(1) |
| IsEmpty | 0(1) | 0(1) | 0(1) |
